

Well, this one is easy....it uses a 2014 Jeep Grand Cherokee.

Truthfully, it really is an easy explanation.

Email is a name of specific type of data. Data is what computers read. The data travels by the same method that is used by the viewing of WEB Sites. You can read about this in the ezipak called "How Does CyberSpace Work?".

Basically, it goes from the program (client) you are using to write it, through cyberspace to the email server. It then sits there until the recipient reads it. Email is accessible from 2 basic areas.....a web site designed to read email, and a local email program on your computer; such as Outlook.

When you write your email, and then click send, it will travel out of your computer to your internet provider. Their computer will then determine the numerical address for the email address you are sending to.

Remember, computers only work with numbers. So all email and web addresses must be converted to their specific numerical address first. This process is too complex to discuss here....sorry.

Your internet provider then sends your email to this numerical address via a specific route, using different communications companies involved with internet traffic.

Easily put, the numerical address represents a physical server. Thus, the data travels to this server via a pre-determined route, basically.

There is more involved with the way it travels, but my fingers are too tired to explain it.

So that's it, in a walnut shell. Did you really expect more?
